

2023 Global DevSecOps Report

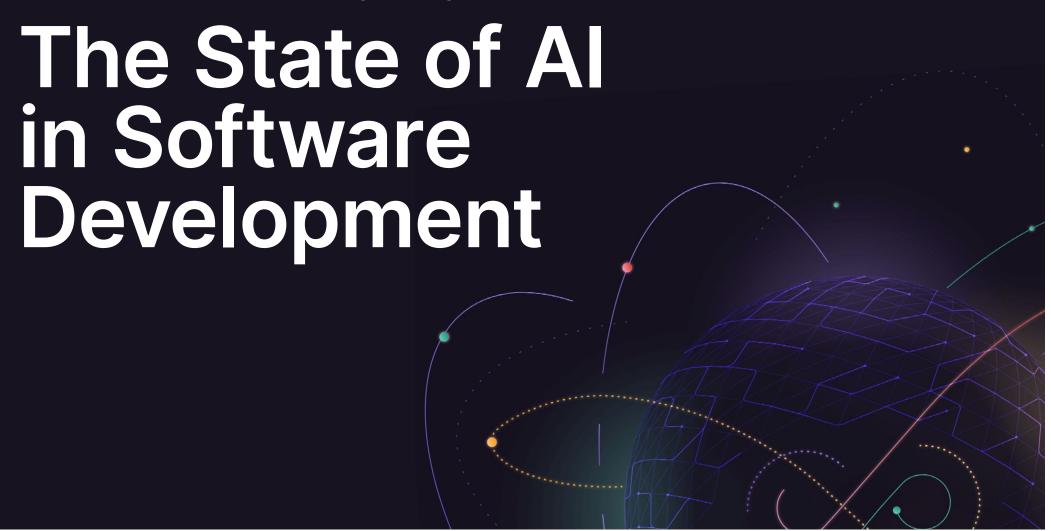

Table of contents

- 03 Executive summary
- 04 Who took the survey?
- 08 Introduction
- 09 Al in the software development lifecycle: Gaining traction
- 12 Code generation the start of a larger shift

- 15 The stumbling blocks: Security, privacy, and IP
- 17 Bridging the skills gap
- 20 Al can't replace human experience

Executive summary

Artificial intelligence (AI) can help development, security, and operations (DevSecOps) teams write code, resolve security vulnerabilities, accelerate code review, and improve collaboration. Our survey suggests DevSecOps teams are feeling optimistic about their adoption of AI and all its potential — but to ensure AI initiatives are successful, organizations will need to examine how AI can support all stages of the software development lifecycle. Respondents also surfaced significant concerns around data privacy, intellectual property, and security.

DevSecOps teams are embracing AI in a big way

of respondents said their organizations are planning to use Al in software development (and 23% are already using it today).

of respondents said it is essential to implement AI in their software development processes to avoid falling behind.

Al needs to support the entire software development lifecycle

of developers' time is spent on tasks other than code generation — suggesting that code generation is only one area where Al can add value.

Top three use cases for AI in software development, according to respondents

Natural-language chatbots

Automated test generation

AI-generated summaries of changes made to code

Data privacy, intellectual property, and security are key areas of concern

of C-level and VP respondents said privacy and protection of intellectual property are important when evaluating an Al tool or feature.

of respondents said they are concerned about AI tools having access to private information or intellectual property.

of security professionals were concerned that Alpowered code generation will increase their workload (compared to just 29% of respondents overall).

Teams feel they lack the skills and training necessary to implement Al

of respondents said they need more training to use Al in their work.

of respondents said their organization has hired or will hire new talent to manage the implementation of Al.

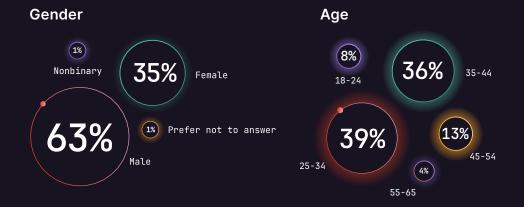

Who took the survey?

We collected a total of 1,001 survey responses in June 2023 from individual contributors and leaders in development, IT operations, and security across a mix of industries and business sizes worldwide.

We used two sampling methods for the data collection:

- 1. We distributed the survey via GitLab's social media channels and email lists.
- 2. A third-party research partner conducted panel sampling, which reduces bias in the sample. Our research partner used its proprietary access to lists, panels, and databases to gather quality responses and cleaned the data throughout fielding to ensure data quality.

Here's a closer look at the survey respondents:

Introduction

Artificial intelligence (AI) has made incredible technological strides in the past several years. From image and text generation to speech recognition, new developments in AI are poised to have a significant impact on virtually every industry — including software development.

The power of AI to shape how teams plan, build, secure, and deploy software is already being tested in the real world. But is AI living up to its promise? How are DevSecOps teams using AI in software development today, and where do they actually *want* to use it? What are organizations hoping to achieve with AI, and what are the tradeoffs? In this special edition of our 2023 Global DevSecOps Report Series, we seek to answer these questions and understand how AI might be able to introduce new efficiencies and opportunities into the software development lifecycle.

First, we'll look at how many organizations are actually using Al today and the benefits they're hoping to drive. We'll also explore how organizations are using Al across the software development lifecycle, and where there are gaps between DevSecOps teams' interest in and current usage of Al. Then we'll turn to the challenges respondents are facing in implementing Al, focusing primarily on concerns around data privacy, intellectual property, security, and training. We'll conclude with a note on why, despite some fears to the contrary, Al can't replace human experience — and how leveraging the experience of human team members alongside Al can help organizations address the concerns that respondents surfaced in our survey.

But first, a note on terminology.

Artificial intelligence is an umbrella term referring to computer software that simulates human capabilities such as logic and problem solving. Machine learning (ML), a subset of AI, is the use of complex mathematical models to enable a computer to identify patterns and make predictions based on existing data. There are also a number of other more specific applications of AI, such as generative AI (a form of AI that generates new, original content based on patterns in existing data), deep learning (a subset of ML that uses complex layers of ML algorithms to carry out sophisticated tasks), and natural language processing (a subset of AI that focuses on building systems that can understand language using ML). Throughout this report, we'll use the broadest term, AI, to cover all of these applications.

Now, let's dive in.

Al in the software development lifecycle: Gaining traction

If there was one inescapable takeaway from the survey data, it's that Al in software development is here to stay. The vast majority (83%) of respondents agreed that it is essential to implement Al in their software development processes to avoid falling behind, and this was consistent regardless of respondents' functional area (development, operations, and security), job level, or years of experience. It's not surprising, then, that most organizations have plans to incorporate Al into software development: 23% of respondents said their organizations are currently using Al in the software development lifecycle, and 67% said their organizations are planning to do so.

Is your organization using or planning to use AI in the software development lifecycle?

	23%
Yes, we are currently using AI in the software development lifecycle	
	19%
Yes, in the next year	
	22%
Yes, in 1-2 years	
	11%
Yes, in more than 2 years	
	15%
Yes, but there is no specific timeline	
	8%
No, the organization has no plans to introduce AI into the software development lifecycle	
	1%
No, the organization has explicitly prohibited the use of AI in the software development lifecycle	

However, Al isn't just another fad — it's seeing real adoption among practitioners. A solid majority (75%) of respondents whose organizations are using Al or planning to use Al for software development said at least a quarter of their DevSecOps team members currently have access to Al tools or functionality. For these teams, Al is becoming embedded in their day-to-day responsibilities: Among respondents whose organizations are using Al in software development today, 60% said they use Al daily, and 22% said they use Al several times a week. This was consistent across development, operations, and security, although respondents with five or fewer years of experience in their functional area were significantly more likely to use Al on a daily basis than more experienced respondents.

Frequency of AI usage, according to respondents whose organizations are using AI in software development today

Promisingly, the vast majority of respondents whose organizations are using AI today (90%) said they feel confident using AI in their daily tasks at work, and more than half (51%) rated their organization's efforts in incorporating AI into the software development lifecycle as "very" or "extremely" successful. In addition, it's clear that organizations as a whole agree that AI is an important investment. Among respondents whose organizations are using AI or plan to in the future, 83% said they have or will have budget specifically allocated to AI for software development.

What's driving the widespread adoption of AI? Respondents whose organizations are using AI now or plan to use AI in the future identified improved efficiency (55%), faster cycle times (44%), and increased innovation (41%) as the top organizational benefits of introducing AI into the software development lifecycle.

What benefits does your organization associate with using AI in the software development lifecycle?

	55%
Improved efficiency	
	44%
Faster cycle times	
	41%
Increased innovation	
	40%
Improved employee productivity	
	40%
Improved security	
	39%
Faster time to market/increased business agility	
	37%
Increased revenue	
	36%
Improved customer satisfaction	
	29%
Improved employee satisfaction	
	26%
Improved customer retention	
	24%
Improved employee retention	

Different functional areas and job levels identified slightly different benefits from adopting Al. For example, developers (48%) were significantly more likely than security respondents (38%) to identify faster cycle times as a benefit of Al. Similarly, respondents with five or fewer years of experience (50%) were more likely than more experienced respondents (42%) to choose faster cycle times.

Security emerged as a key organizational benefit of Al overall, making the top five, and this was particularly true for managers and executives. Respondents with C-level/VP (46%) or manager titles (43%) were significantly more likely than non-managers (34%) to identify improved security as a benefit.

What benefits have you personally achieved or do you hope to achieve by using Al in the software development lifecycle?

	51%
Improved productivity	
	44%
Faster deployments/software releases	
	40%
Increased accuracy, fewer errors	
	40%
More intelligent monitoring and alerting	
	40%
Improved ability to predict potential issues, identify patterns, and make data-driven decisions	
	38%
Enhanced quality assurance	
	36%
Career growth/learning new skills	
	35%
Improved collaboration	
	32%
Feeling more satisfied at work	

Respondents identified similar benefits when asked what they have personally achieved or hope to achieve by adopting AI in the software development lifecycle, with improved productivity (51%), faster deployments (44%), and increased accuracy (40%) rounding out the top three.

Interestingly, general benefits related to work experience, such as feeling more satisfied at work (32%) and learning new skills (36%), ranked relatively low, although respondents with five or fewer years of experience (41%) were more likely than more experienced respondents (33%) to choose career growth. This suggests that while DevSecOps teams see Al as a utility that assists with their day-to-day work, this doesn't necessarily translate (or isn't expected to translate) into improved work satisfaction for everyone. One explanation is that Al needs to be more uniformly integrated across the entire software development lifecycle — more on that in the next section.

Next, let's explore where respondents are using Al today, where they're interested in using Al, and where in the software development lifecycle Al has the potential to have the biggest impact.

"The role of software developers is evolving because of Al. It can help them with their code, but we're years away from Al being able to write code completely on its own or replace developers."

- Executive in the computer/SaaS industry

Code generation — the start of a larger shift

Generative AI has important applications in software development. By using AI to suggest common lines of code or generate logic for function declarations, developers can boost their accuracy, efficiency, and productivity.

Given that generative AI has been in the spotlight for much of this year, it's no surprise that DevSecOps teams are curious about how it might be able to help them accelerate code creation. In fact, code generation and code suggestions (55%) topped the list of software development use cases where respondents were interested in applying AI, closely followed by forecasting of productivity metrics and identification of anomalies (54%), summaries of code changes (53%), and explanations of how a piece of code works (53%).

For which of the following use cases is your organization interested in using AI in the software development lifecycle?

	55%
Code generation and code suggestions	
	54%
Forecasting of productivity metrics and identification of anomalies across the software development lifecycle	
	53%
Summaries of code changes	
	53%
Explanations of how a piece of code works	
	52%
Suggestions for who can review code changes	
	52%
Summaries of issue comments	
	52%
Explanations of how a vulnerability can be exploited and how to remediate it	
	50%
Automated test generation	
	50%
Tracking machine learning model experiments	
	48%
Chatbots that allow users to ask questions in	

However, when we look at how respondents said they're using Al today, we get a slightly different picture. The top ways respondents said they are currently using Al for software development were natural-language chatbots in documentation (41%), automated test generation (41%), and summaries of code changes (39%).

For which of the following use cases is your organization currently using Al in the software development lifecycle?

	41%
Chatbots that allow users to ask questions in documentation using natural language	
	41%
Automated test generation	
	39%
Summaries of code changes	
	38%
Tracking machine learning model experiments	
	37%
Suggestions for who can review code changes	
	37%
Summaries of issue comments	
	36%
Code generation and code suggestions	
	36%
Explanations of how a piece of code works	
	36%
Explanations of how a vulnerability can be exploited and how to remediate it	
	35%
Forecasting of productivity metrics and identification of anomalies across the software development lifecycle	

Our survey findings suggest that although code generation is important, it's only one area where AI can potentially add value. Developers reported spending only 25% of their total work time writing code, with the rest spent improving existing code (17%), understanding code (14%), testing (11%), maintaining code (9%), and identifying and mitigating security vulnerabilities (7%). That's nearly 60% of developers' day-to-day where AI — in the form of vulnerability explanations, code change summaries, automated tests, and more — can introduce efficiencies and boost productivity and collaboration.

Amount of time developers report spending on daily tasks

Respondents also identified several concerns around generative AI in the context of code creation. More than half (57%) of respondents said they think AI will replace their role within the next five years. In addition, among the 32% of respondents who expressed concern about introducing AI into the software development lifecycle, two of the top three specific concerns were related to code generation: code generated using AI may not be subject to the same copyright protection as human-generated code (48%) and code generated using AI may introduce security vulnerabilities (39%).

It's apparent that DevSecOps teams see the bigger picture: From test generation to vulnerability analysis to summaries of issue comments, 50% or more of respondents expressed interest in a number of Al-powered use cases beyond code generation. In other words, there's a strong appetite for more — and more integrated — Al spanning the breadth of the software development lifecycle.

Looking at the gaps between respondents' interests and current usage helps us see exactly how much opportunity there is for Al across the software development lifecycle. After code generation, forecasting productivity metrics and anomalies represents the next biggest area of demand, with 54% of respondents saying they are interested, but only 35% saying they are doing it today.

As DevSecOps teams capitalize on these opportunities and Al becomes more embedded in software development workflows, where are they expecting challenges? Next, we'll dive deeper into where respondents expressed concerns about incorporating Al into the software development lifecycle, and what we can learn from the common themes that emerge.

"Testing and quality assurance can benefit the most from AI, as intelligent algorithms can spot bugs and errors that humans might miss."

The stumbling blocks: Security, privacy, and IP

As we've seen, respondents expressed mostly positive sentiments about AI and their organizations' use of AI in software development; however, concerns around privacy, intellectual property, and security emerged repeatedly, suggesting that organizations should seriously consider these areas when implementing AI initiatives.

Overall, nearly a third (32%) of respondents said they were "very" or "extremely" concerned about AI being introduced into the software development lifecycle, while 23% were "not very" or "not at all" concerned. As mentioned above, when asked to identify specific areas of concern, respondents pointed to ambiguities in copyright protection (48%) and the potential to introduce security vulnerabilities (39%) as two of the top concerns.

Continuing the security theme, concern that the use of AI will increase professionals' workload was particularly prevalent among security professionals: 40% of security professionals said they were concerned that AI-powered code generation will add more to their plate, compared to just 29% of respondents overall.

What are your biggest concerns around introducing Al into the software development lifecycle?

	48%
Code generated using AI may not be subject to the same copyright protection as human-generated code	
	42%
AI will introduce a new set of skills to learn	
	39%
Code generated using AI may introduce security vulnerabilities	
	37%
AI will make it difficult to find a job	
	36%
AI will replace or eliminate my job	
	34%
People that I work with will introduce errors using AI, which will make my job more difficult	
	29%
Al-newened code generation will increase my wentlood	

In addition, the vast majority of respondents (79%) said they are concerned about Al tools having access to private information or intellectual property. Among these respondents, the top reason for concern was, by far, that sensitive information such as customer data may be exposed (72%).

Why are you concerned about AI tools having access to private information?

	72%
Sensitive information (such as customer data) may be exposed	
	48%
Trade secrets (such as product plans or source code) may be exposed	
	48%
It is unclear how the data will be stored	
	43%
It is unclear how the data will be used	

Privacy, security, and intellectual property also emerged as common themes in the obstacles respondents said they have encountered or expect to encounter while implementing AI in the software development lifecycle. Concern around privacy and data security (37%) was the top obstacle identified by respondents, followed by security vulnerabilities in software built using AI (35%). Nearly a third (32%) of respondents pointed to copyright and intellectual property.

"Al will have the biggest impact on overall planning and monitoring/ prioritizing the software development cycle. It's pretty harmless to have Al help to keep things on track, but I personally wouldn't trust it to write code due to the risk of bugs or fundamental flaws in logic.

- Software engineer in the computer/SaaS industry

What obstacles has your organization encountered or do you expect will encounter regarding the use of Al in the software development lifecycle?

	37%
Concerns around privacy and data security	
	35%
Concerns around security vulnerabilities in software built using AI	
	34%
Lack of appropriate skill set to employ AI or interpret AI output	
	33%
Lack of knowledge about AI	
	32%
Difficulty keeping up with the latest developments in AI	
	32%
Concerns around copyright and intellectual property	
	32%
Lack of confidence in AI-generated output	
	30%
Concerns around complying with government regulations related to AI	
	26%
Accelerated code creation causing problems for security and operations teams	
	24%
Difficulty procuring tools (securing legal approval, etc.)	
	24%
Difficulty securing budget	

Given these concerns, it's not surprising that an overwhelming 90% of respondents said that privacy and protection of intellectual property are important to them when evaluating an Al tool or feature for use in the software development lifecycle. This was particularly true for executives: 95% of C-level and VP respondents said they prioritize privacy and protection of intellectual property when selecting an Al tool.

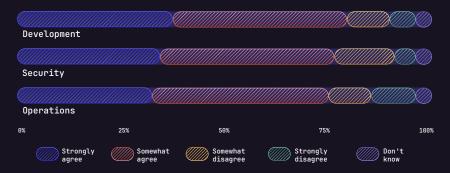

Bridging the skills gap

Training and skills also emerged as a common theme in the obstacles and concerns identified by respondents: A lack of the appropriate skill set to use AI or interpret AI output was one of the top obstacles (34%) and AI introducing a new set of skills to learn was one of respondents' top areas of concern (42%). Clearly, despite overall optimism about AI in software development, DevSecOps professionals feel a pressing need to grow and maintain their skills to stay ahead.

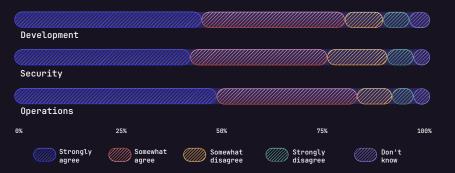

An overwhelming 81% of respondents agreed that they need more training to use AI at work, and 87% said organizations will need to re-skill employees to adapt to the changes AI will bring. This was largely consistent across functional areas, job levels, and organization sizes, although operations respondents (91%) were significantly more likely to agree that organizations will need to re-skill employees than either developers (85%) or security respondents (83%)

Percentage of respondents in Development, Security, and Operations who agreed with the following statements:

I feel I need more training to use AI at work

Organizations will need to re-skill employees to adapt to the changes AI will bring

To address the lack of in-house skills, 65% of respondents said their organization has hired or will hire new talent to manage the implementation of AI in the software development lifecycle.

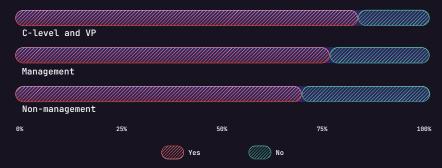

When we asked respondents what types of resources they are using to build their skills in AI, the top responses were books, articles, and online videos (49%), educational courses (49%), practicing with open-source projects (47%), and learning from peers and mentors (47%).

What types of resources do you use to learn about AI?

	49%
Books, articles, and online videos	
	49%
Educational courses	
	47%
Practicing with open-source projects	
	47%
Learning from peers and mentors	
	43%
News websites	
	34%
Vendor resources	

The vast majority of respondents (75%) told us their organization provides training and resources for using AI — but C-level respondents (85%) and respondents with manager titles (78%) were significantly more likely than non-managers (69%) to say their organization provides training and resources for using AI. This suggests that although organizations are making a top-down attempt to make AI resources available to employees, those resources may not be adequate, or some employees may not be aware of them.

Does your organization provide training and resources for using AI?

Interestingly, despite three-quarters of respondents saying their organization provides training and resources for using AI, a roughly equal proportion also said they are finding resources on their own, further suggesting that the currently available resources and training may be insufficient. Developers (82%) were significantly more likely than either security (69%) or operations respondents (74%) to report finding AI resources on their own.

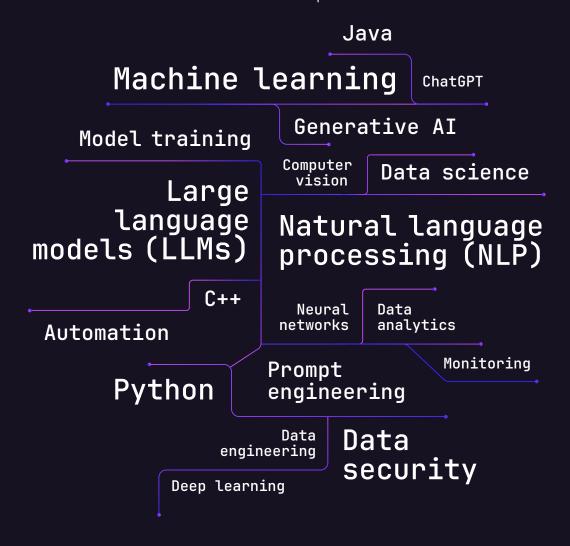

Are you finding training and resources on your own for using AI?

This makes sense, as developers are likely to be more hands-on with generative Al use cases that require training to use effectively. Developers were also significantly more likely to lack confidence in Al-generated output than either security or operations respondents (38% versus 28% and 28%, respectively). While organizations should focus on providing Al training and resources to all job roles and functional areas that will be using Al, it may be especially important to ensure that the resources for development teams are relevant, up to date, and cover the latest Al technologies and applications.

What AI-related skills would you like to learn as part of your career development?

We asked respondents to share, in their own words, how they'd like to build their Al skills. Here are a few of the most common responses:

Al can't replace human experience

DevSecOps professionals are in agreement that AI has the power to boost their teams' productivity and efficiency, and that it will be essential for them to build and maintain AI skills to stay competitive as individuals. At the same time, they acknowledge the inherent limitations of AI — such as the potential to introduce security risks — and the need for human review of AI-generated output.

One respondent, a DevOps engineer in the financial services industry, summed up DevSecOps teams' cautious optimism towards AI: "Given current levels of AI, I would argue that simple, repeatable tasks are the best way forward. Everything else requires human interaction and review. I think AI can help speed up some tasks, but the humans involved have to be aware and responsible for what the AI is generating." Another respondent, a quality assurance associate in the software industry, wrote: "I think AI could be beneficial in many areas, but it's important to not lose a personal touch and connection."

As organizations work to embed AI more deeply into their workflows, a tension is emerging between promises and reality — with human expertise as the inflection point. In our survey, more experienced respondents were less likely to associate AI with value drivers such as productivity gains and faster cycle times. One explanation is that more experienced DevSecOps professionals accept AI as a supportive tool for skill development, but don't think it can completely replace the expertise, knowledge, and problem-solving of seasoned professionals like themselves. Conversely, DevSecOps professionals who are newer to the field may have more confidence in AI, perhaps because of their exposure to the technology through their schooling or on-the-job training.

Ultimately, however, it comes down to more than simply human versus machine. Leveraging the experience of human team members alongside AI is the best — and perhaps only — way organizations can fully address the concerns around security and intellectual property that emerged repeatedly in our survey data. AI may be able to generate code more quickly than a human developer, but a human team member needs to verify that the AI-generated code is free of errors, security vulnerabilities, or copyright issues before it goes to production. As AI comes to the forefront of software development, organizations should focus on optimizing this balance between driving efficiency with AI and ensuring integrity through human review.

GitLab
